

Modern SOC: Less Than One and  
More Than Infinity

2024

CODEBLUE

BECAUSE SECURITY MATTERS

---

# Modern SOC: Less Than One and More Than Infinity

Alexander Rodchenko

Senior SOC Analyst at SOC  
Security Research Group

[@Gam4enko](#)

# Agenda

Highlight parts

- Problem definition. SOC vs with Classic Protection.
- 3 Examples of threats that only SOC can protect against.
  1. **Classification**
  2. Examples of Code for Protection
- Conclusions, Generalizations, Opportunity for Discussion
- Several notes
- Questions

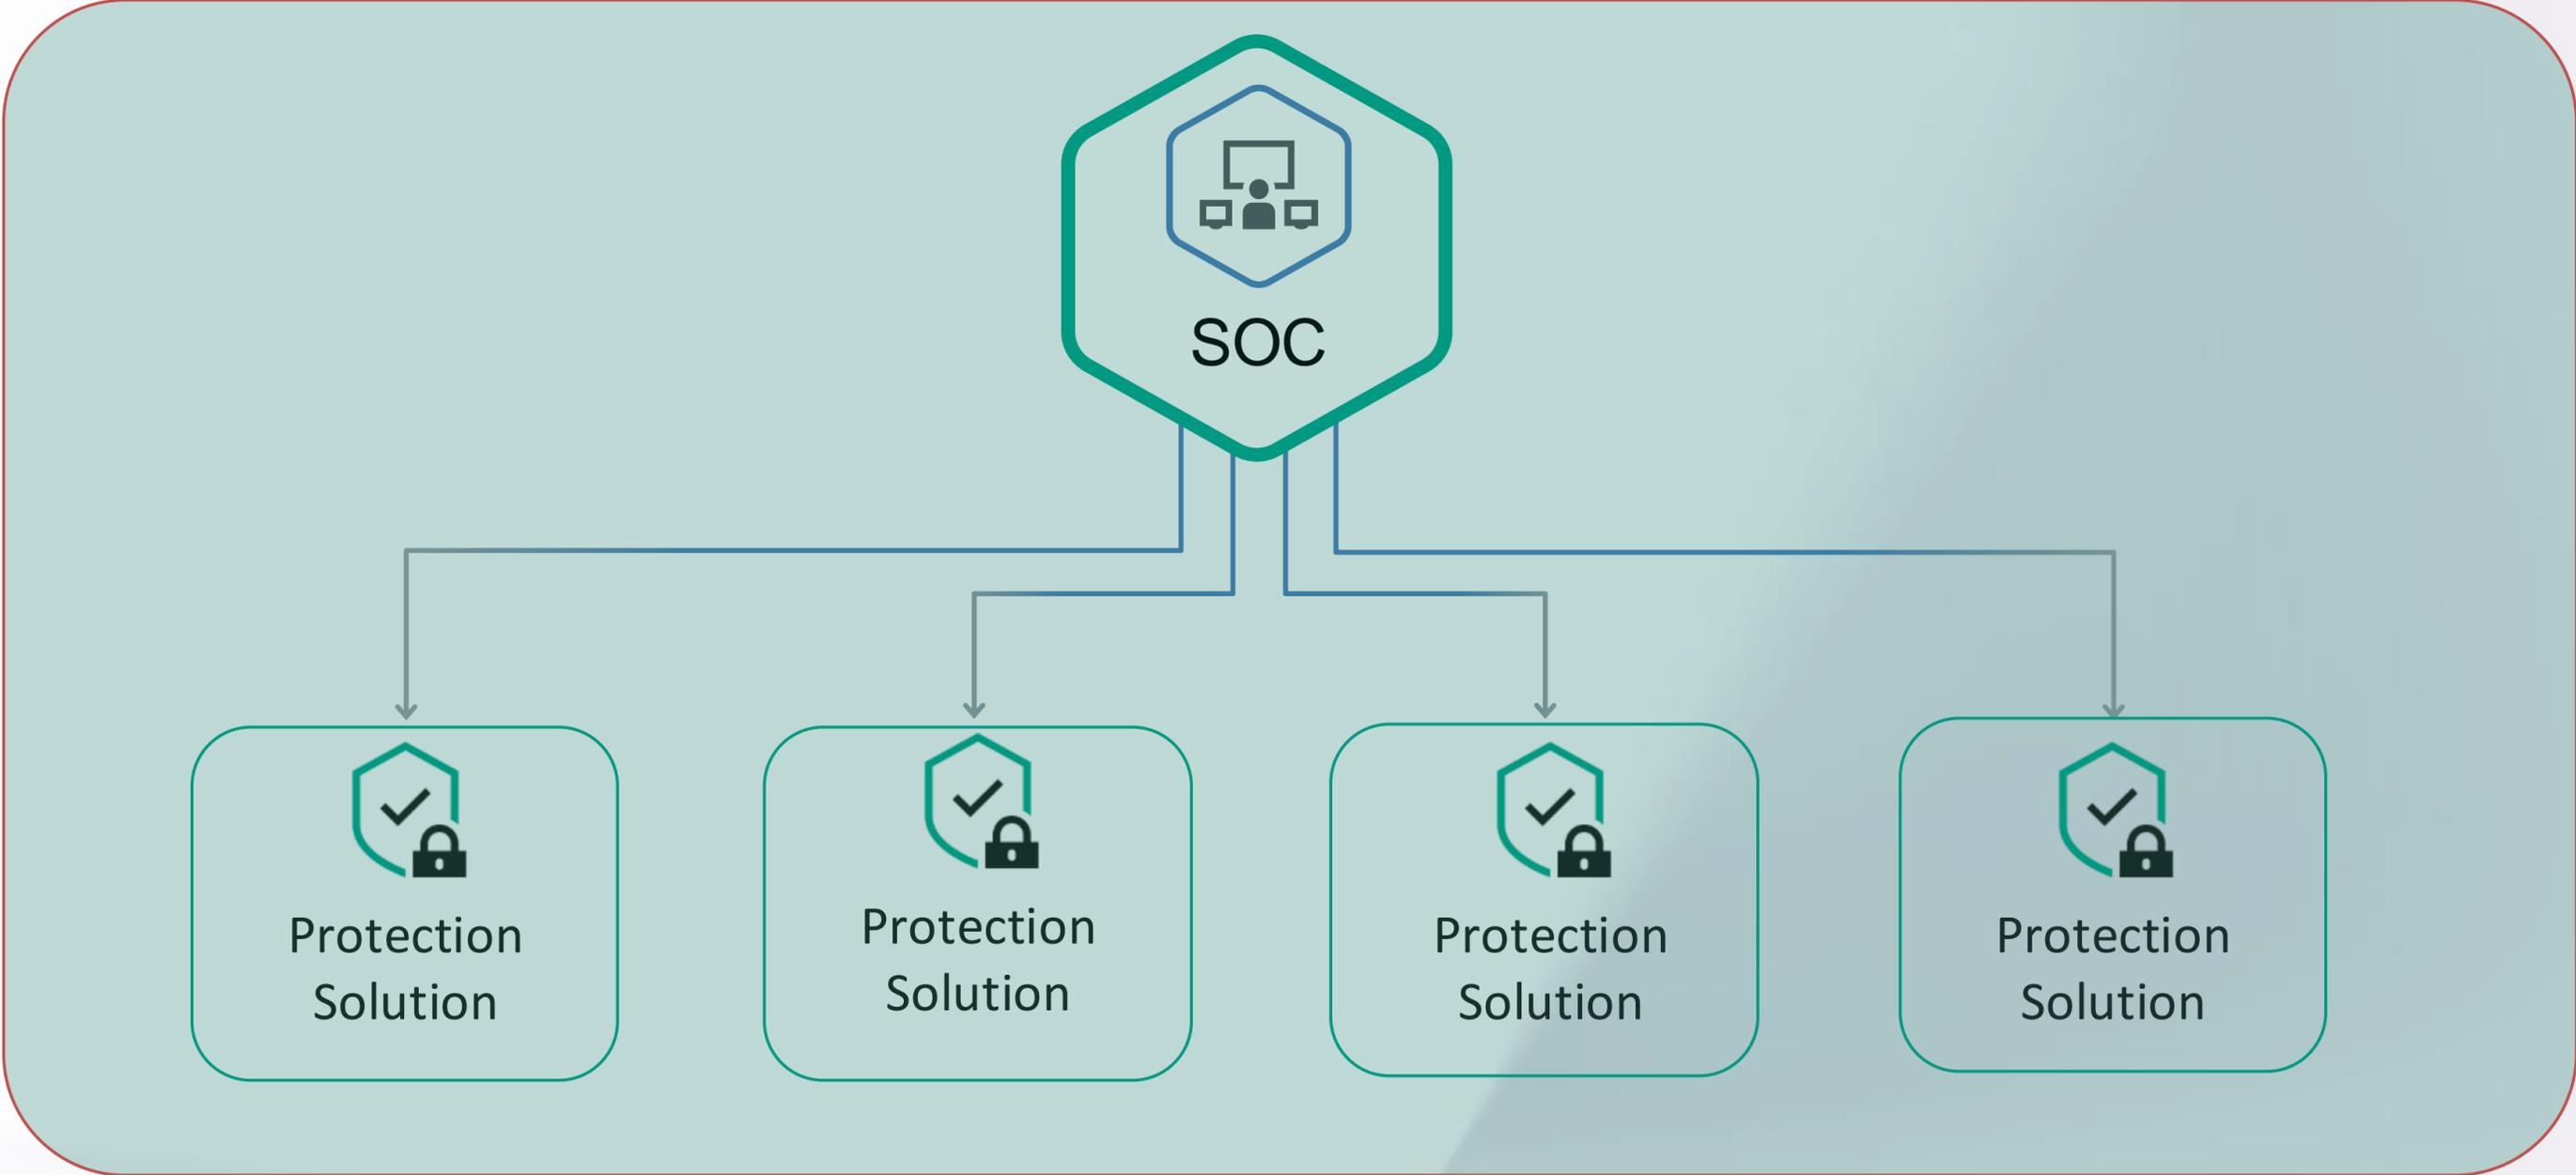

**This is not a complete definition, however, it is undoubtedly true.**

Classical Security Products	SOC
Focus primarily on productivity and <b>prevention</b>	Prioritizes the client's <b>context</b> , protecting the client rather than just the computer
Rely heavily on <b>signatures, patterns, and heuristics</b> to detect known threats.	Employs <b>flexible</b> and adaptive <b>methods</b> for manipulating telemetry data to detect anomalies

Traditional security solutions focused on prevention and detection through signatures and patterns, serving as **fundamental tools for SOC operations.**

A centralized security **function** that continuously monitors and responds to cyber threats using **adaptive techniques** tailored to the organization's specific **context.**

He that breaks a thing to find out what it is has left the path of wisdom.

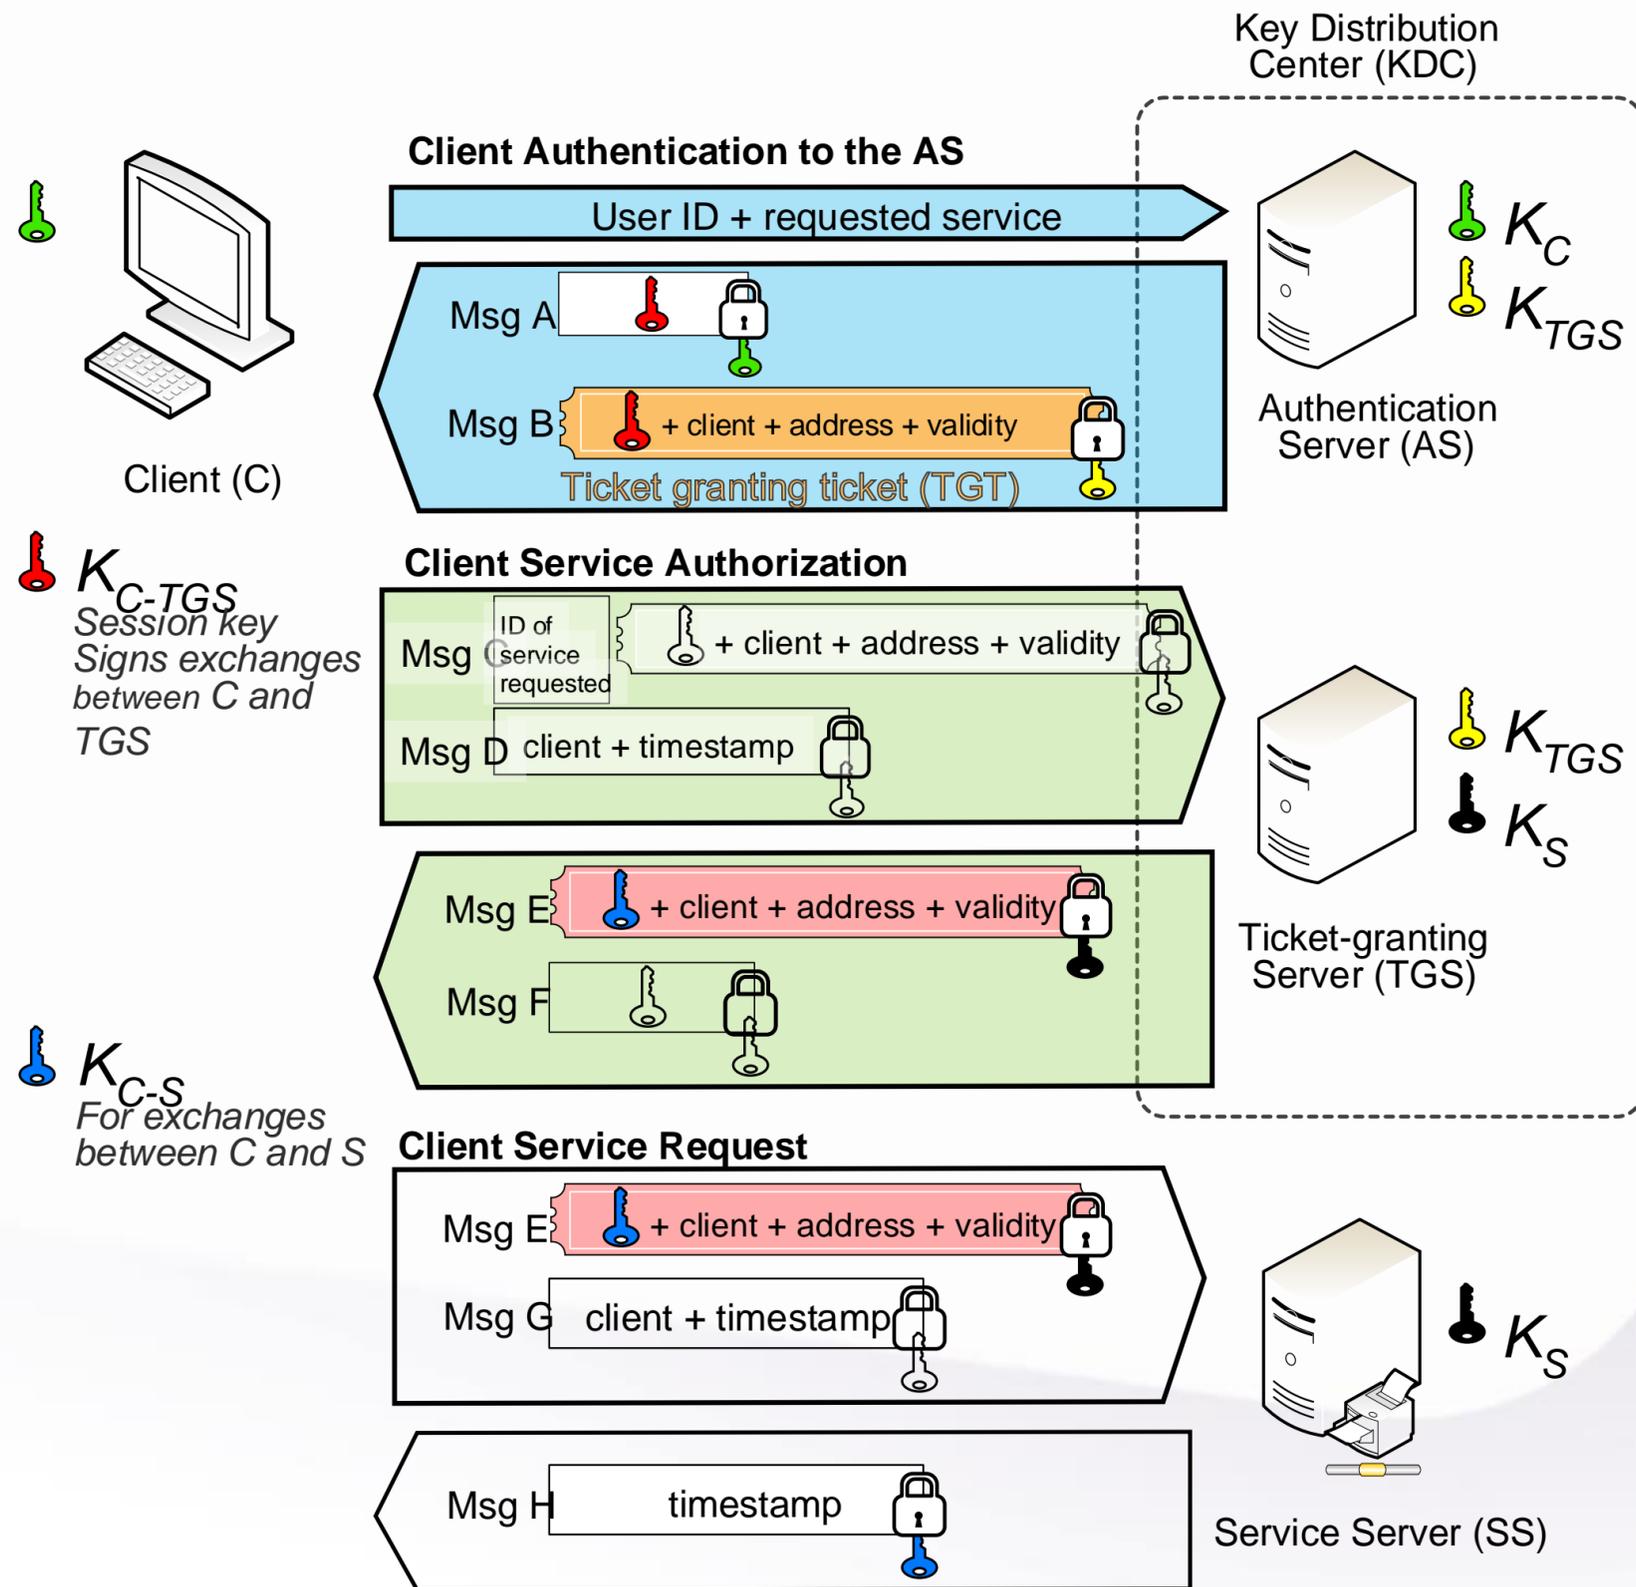

Gandalf speaking to Saruman

Let's break down the method for **detecting a Golden Ticket** attack and why this is specifically a **task for the SOC team**.

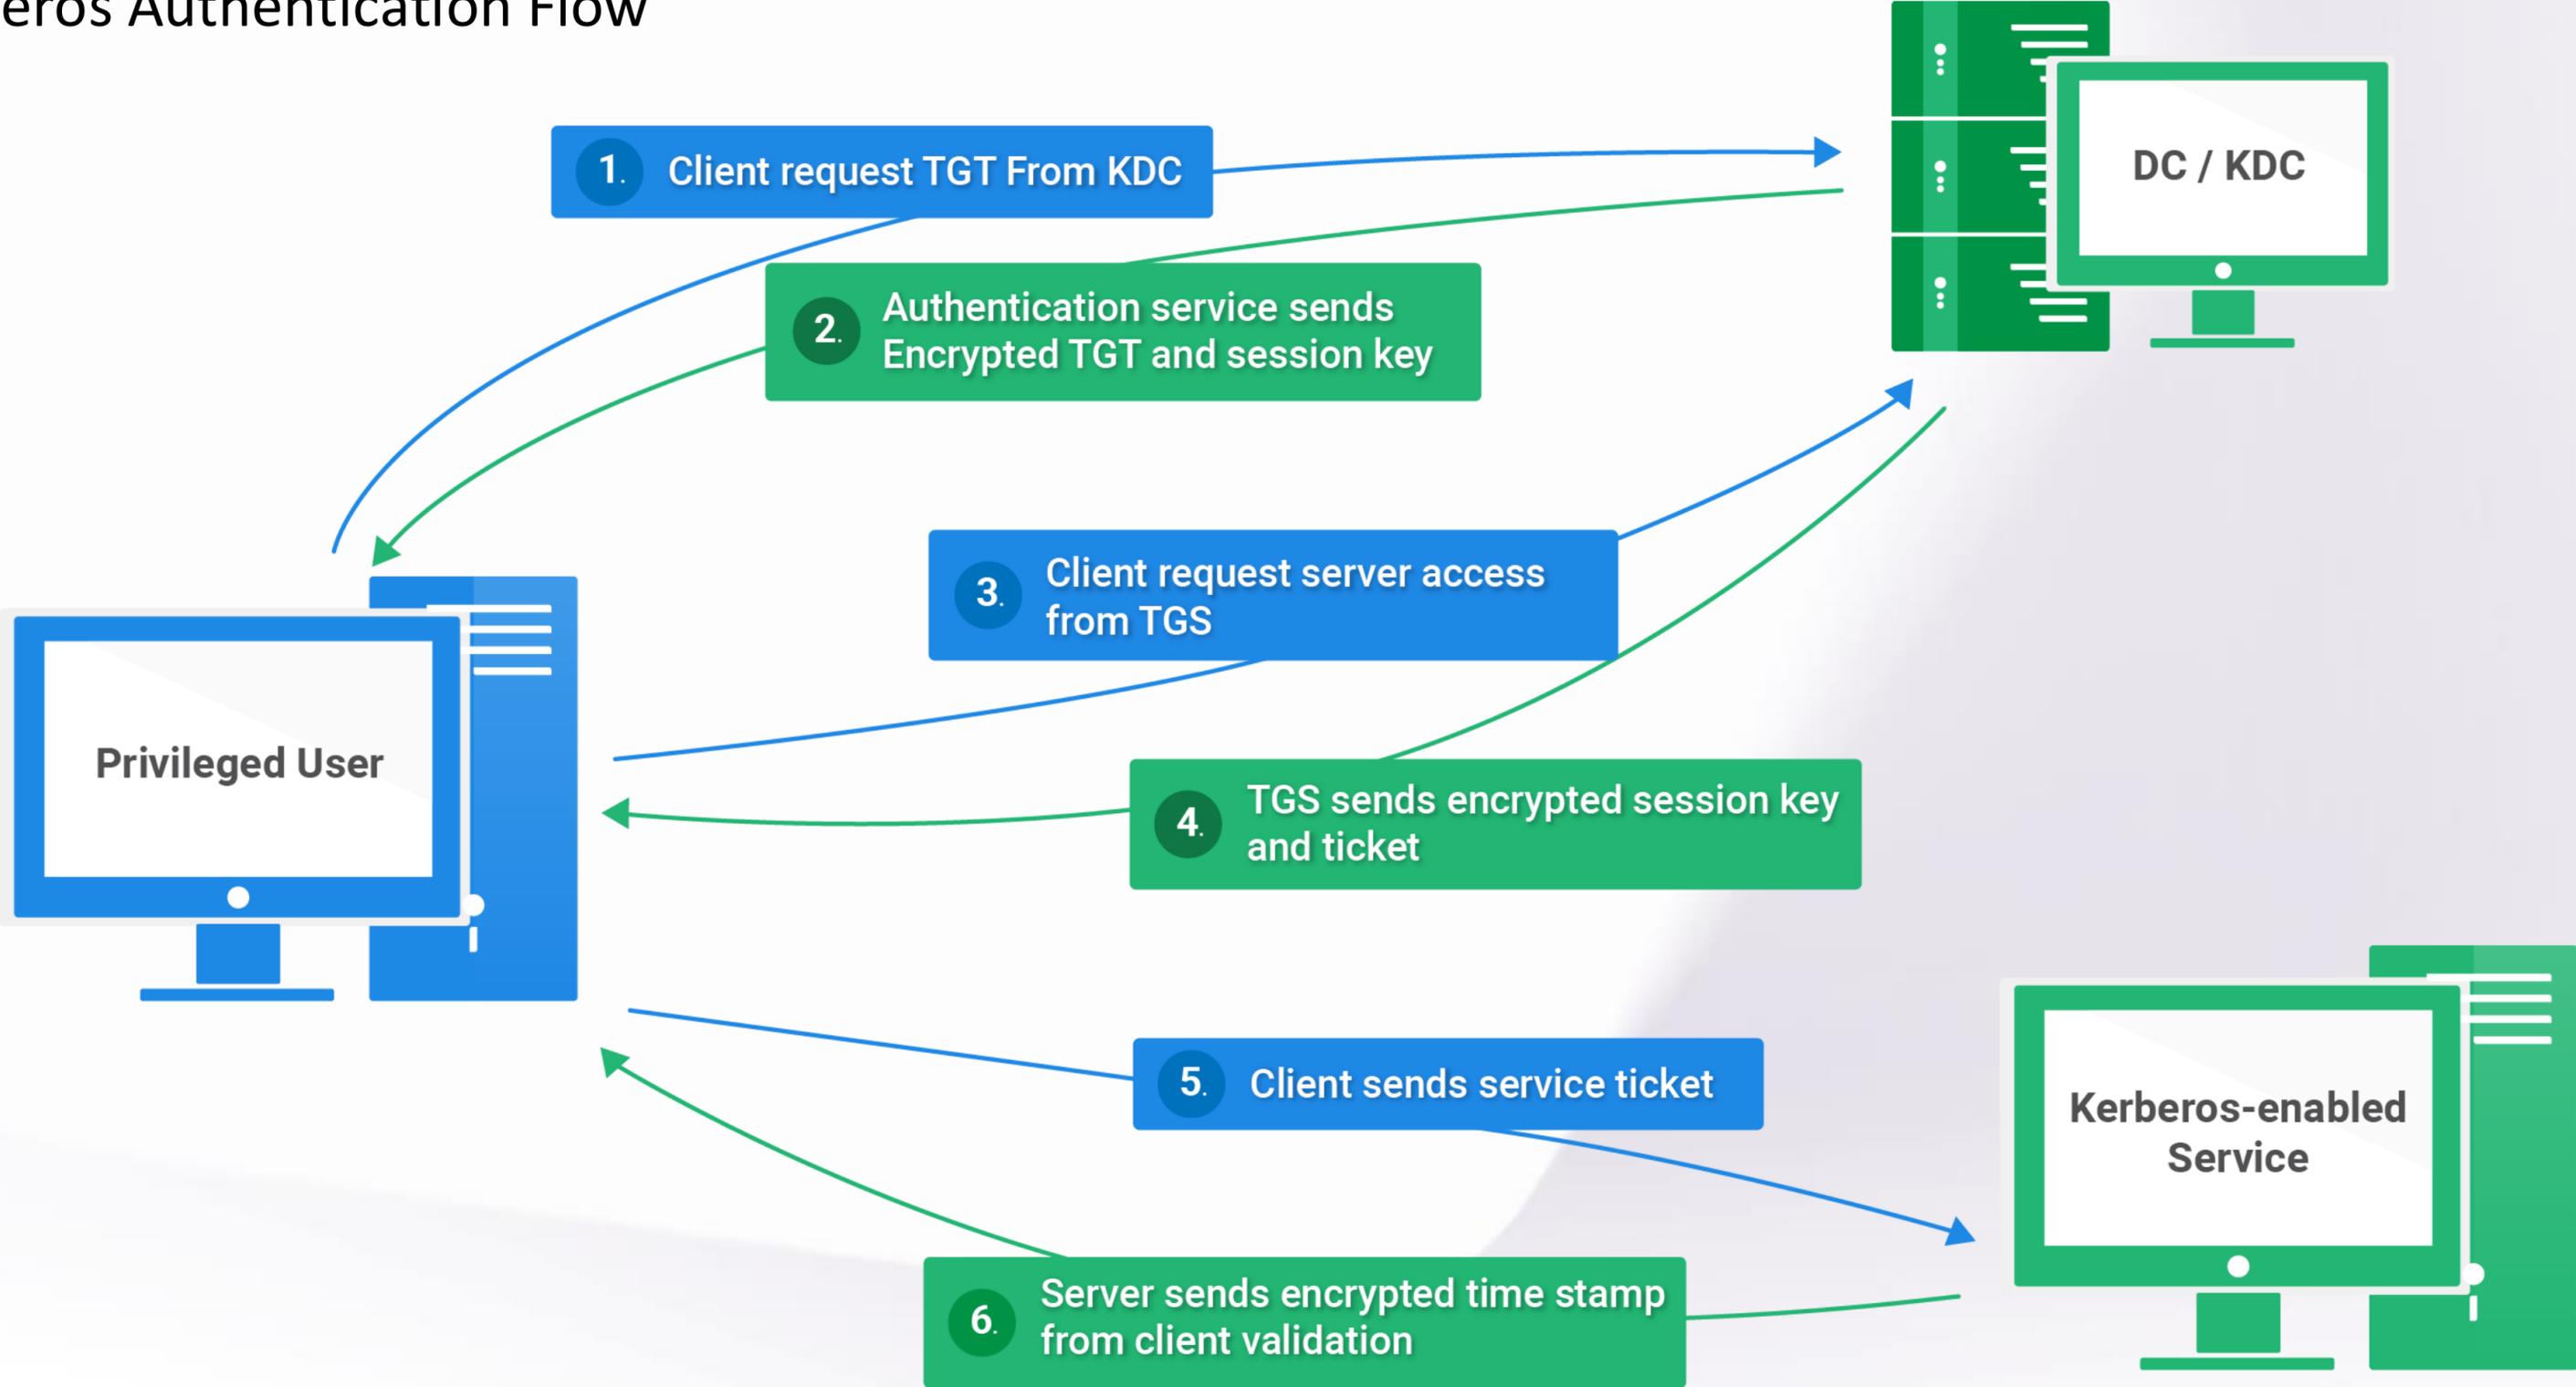

# Kerberos

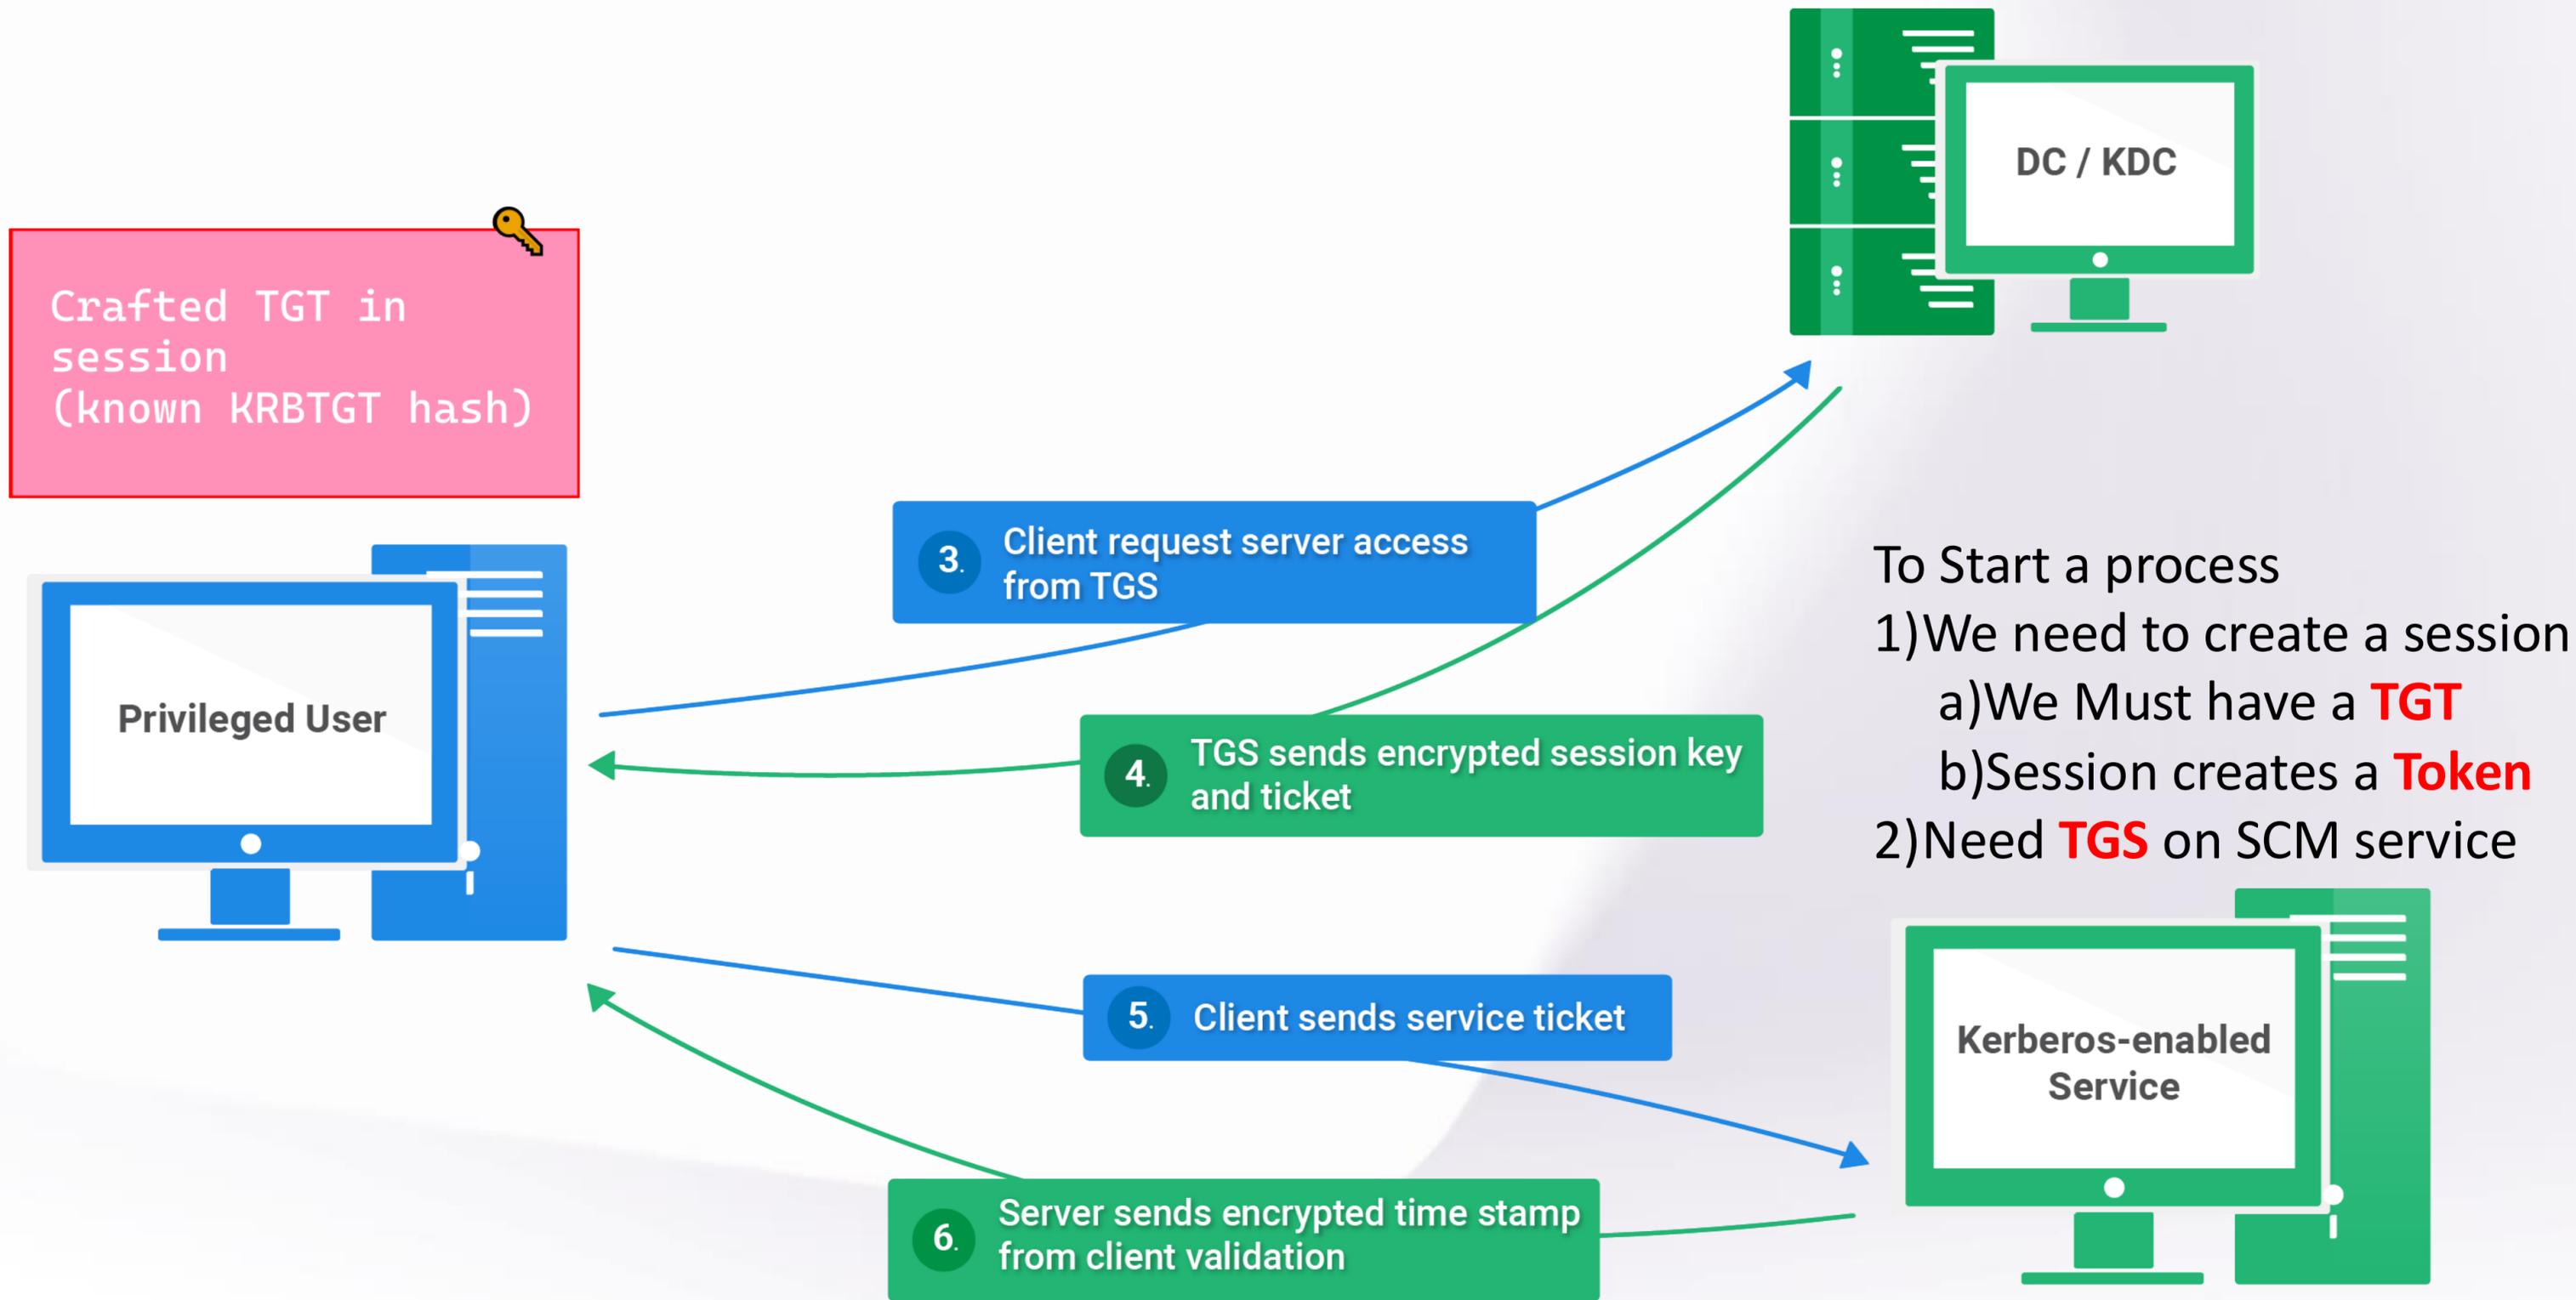

Let's recall the Kerberos page from Wikipedia.

- KDC distributes tickets
- KRBTGT hash – key for KDC

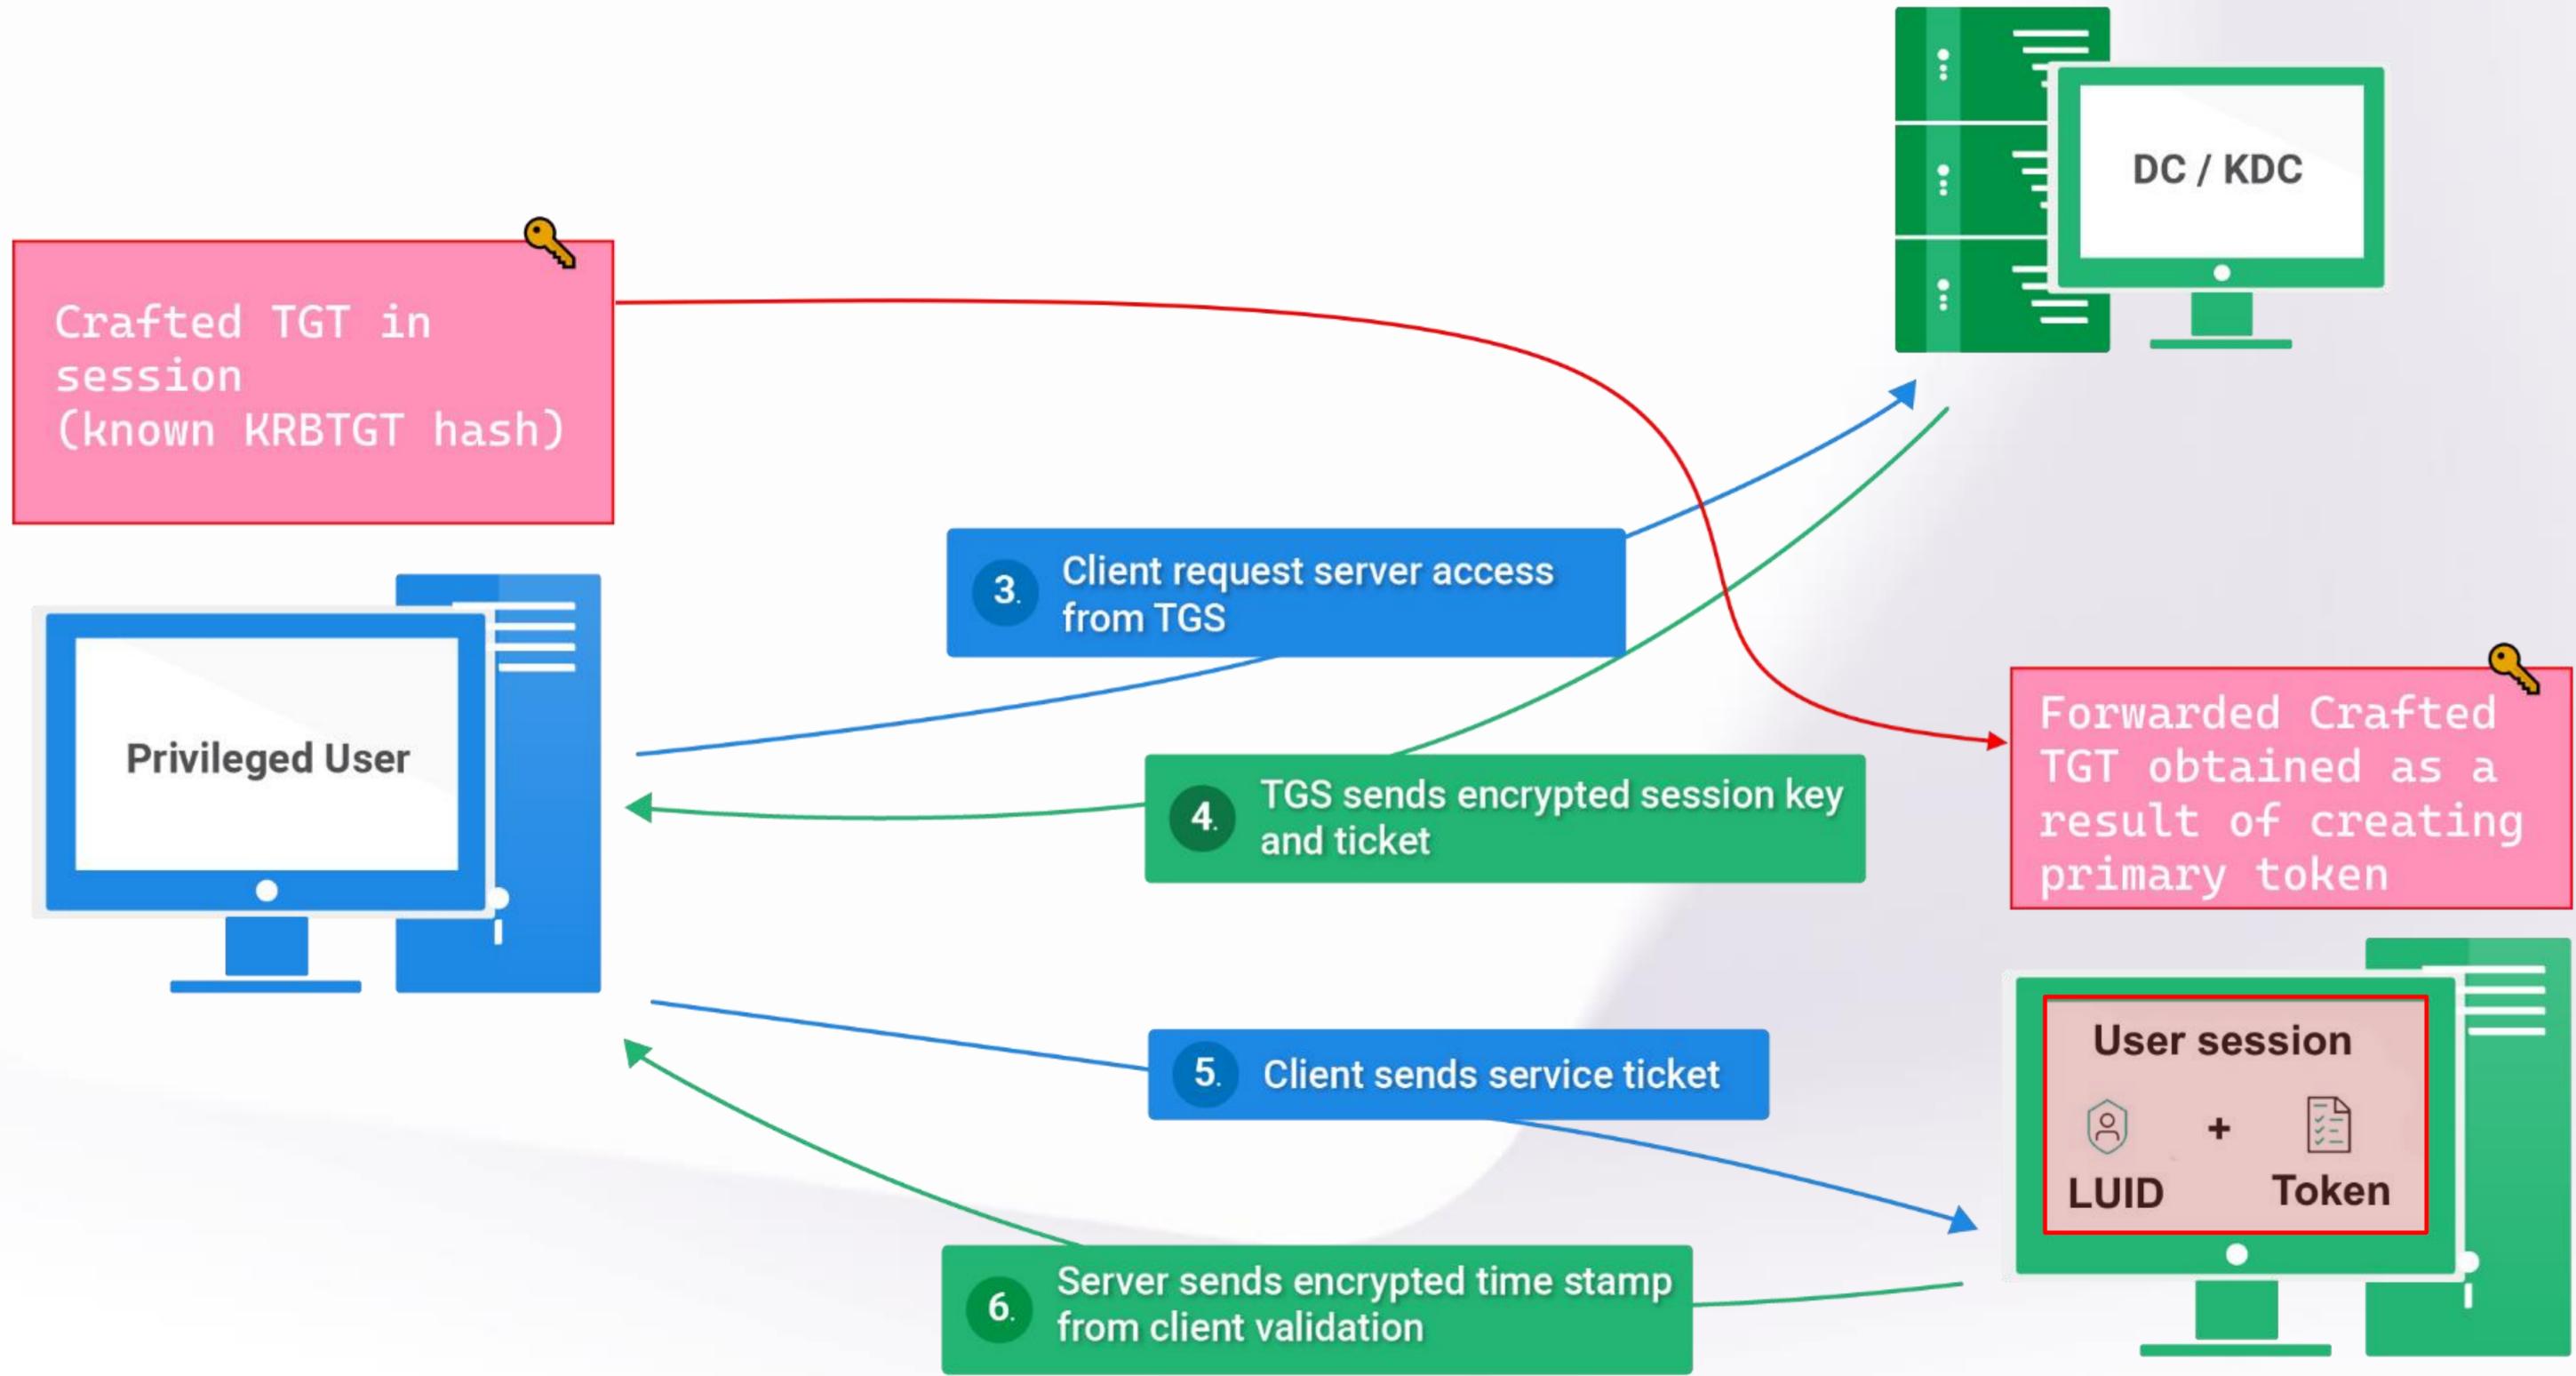

# Kerberos Authentication Flow

# Kerberos Authentication Flow (Try to run cmd via PsExec)

# Kerberos Authentication Flow

Lets Google how (implement best read team practice) and create our own GT

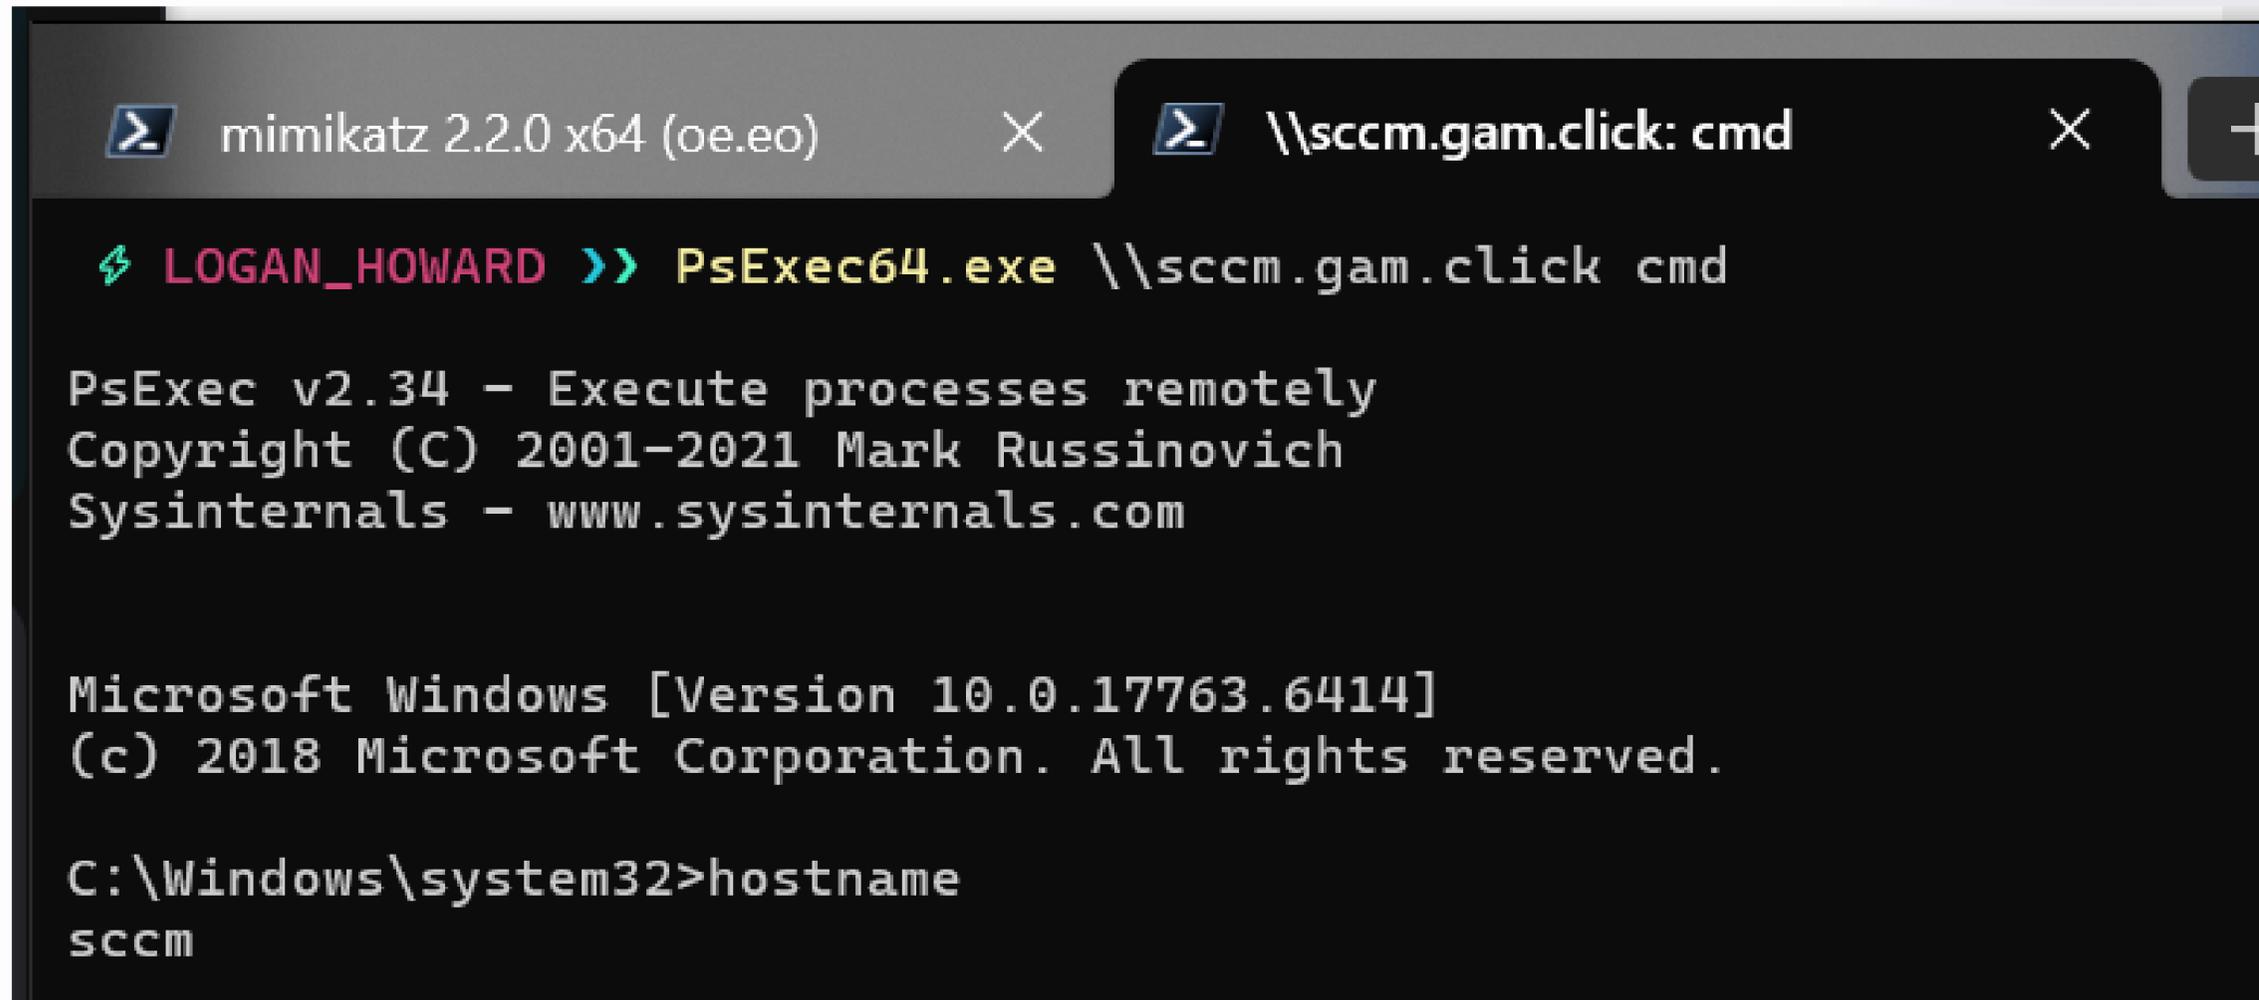

```
mimikatz # kerberos::golden /domain:GAM.CLICK /sid:S-1-5-21-511818909-1338016983-424820340 /rc4:43ad00a8e90d836d3b051c9b28e4abac /user:Administrator /ptt
User      : Administrator
Domain    : GAM.CLICK (GAM)

# Kerberos Authentication Flow (GT Logon token groups)

The screenshot shows the 'Token' tab of the 'cmd.exe (5944) Properties' window. It displays user information and a list of token groups. The user is 'gam\Administrator' with SID 'S-1-5-21-511818909-1338016983-424820340-500'. The session is 0, elevated by default, and virtualized is not allowed. A table lists token groups with columns for Name, Status, Description, SID, Type, and Use. The 'SeDelegateSessionUserImpersonatePrivilege' privilege is enabled. The 'Groups' table includes entries like 'Everyone', 'NT AUTHORITY\NETWORK', and various 'gam\' domain groups. The 'Alias' for the 'gam\Denied RODC Password Replication Group' is highlighted with a red box.

```

# Context paradox

To create detection logic, we sometimes need more context. In this case, we need information from Active Directory.

**Only the SOC** can access this information and accurately process the results.

Let's go over the methods for **monitoring** and **detecting attacks on SCCM** and confirm why this is specifically an area of focus **for SOC**.

System Center Configuration Manager (SCCM) is a systems management software developed by Microsoft that enables administrators to manage large groups of Windows-based computers. SCCM allows for the deployment and management of software, updates, and configurations across a network, providing tools for inventory tracking, application delivery, patch management, and operating system deployment. It is widely used in enterprise environments for automating routine tasks, enforcing security compliance, and maintaining configuration consistency across devices.

SCCM addresses the following tasks:

1. **Software Deployment** – Distributes applications, updates, and patches across devices.
2. **Operating System Deployment (OSD)** – Automates OS installations and upgrades.
3. **Patch Management** – Ensures systems are up-to-date with security and software patches.
4. **Inventory Management** – Tracks hardware and software assets within the network.
5. **Compliance Management** – Enforces security and configuration standards.
6. **Endpoint Protection** – Provides antivirus, antimalware, and security policy management.
7. **Remote Control** – Enables remote troubleshooting and management of devices.
8. **Reporting and Analytics** – Generates detailed reports on device health, compliance, and usage.
9. **Configuration Management** – Manages configurations and settings across devices.
10. **Power Management** – Controls and monitors energy settings to optimize power usage.

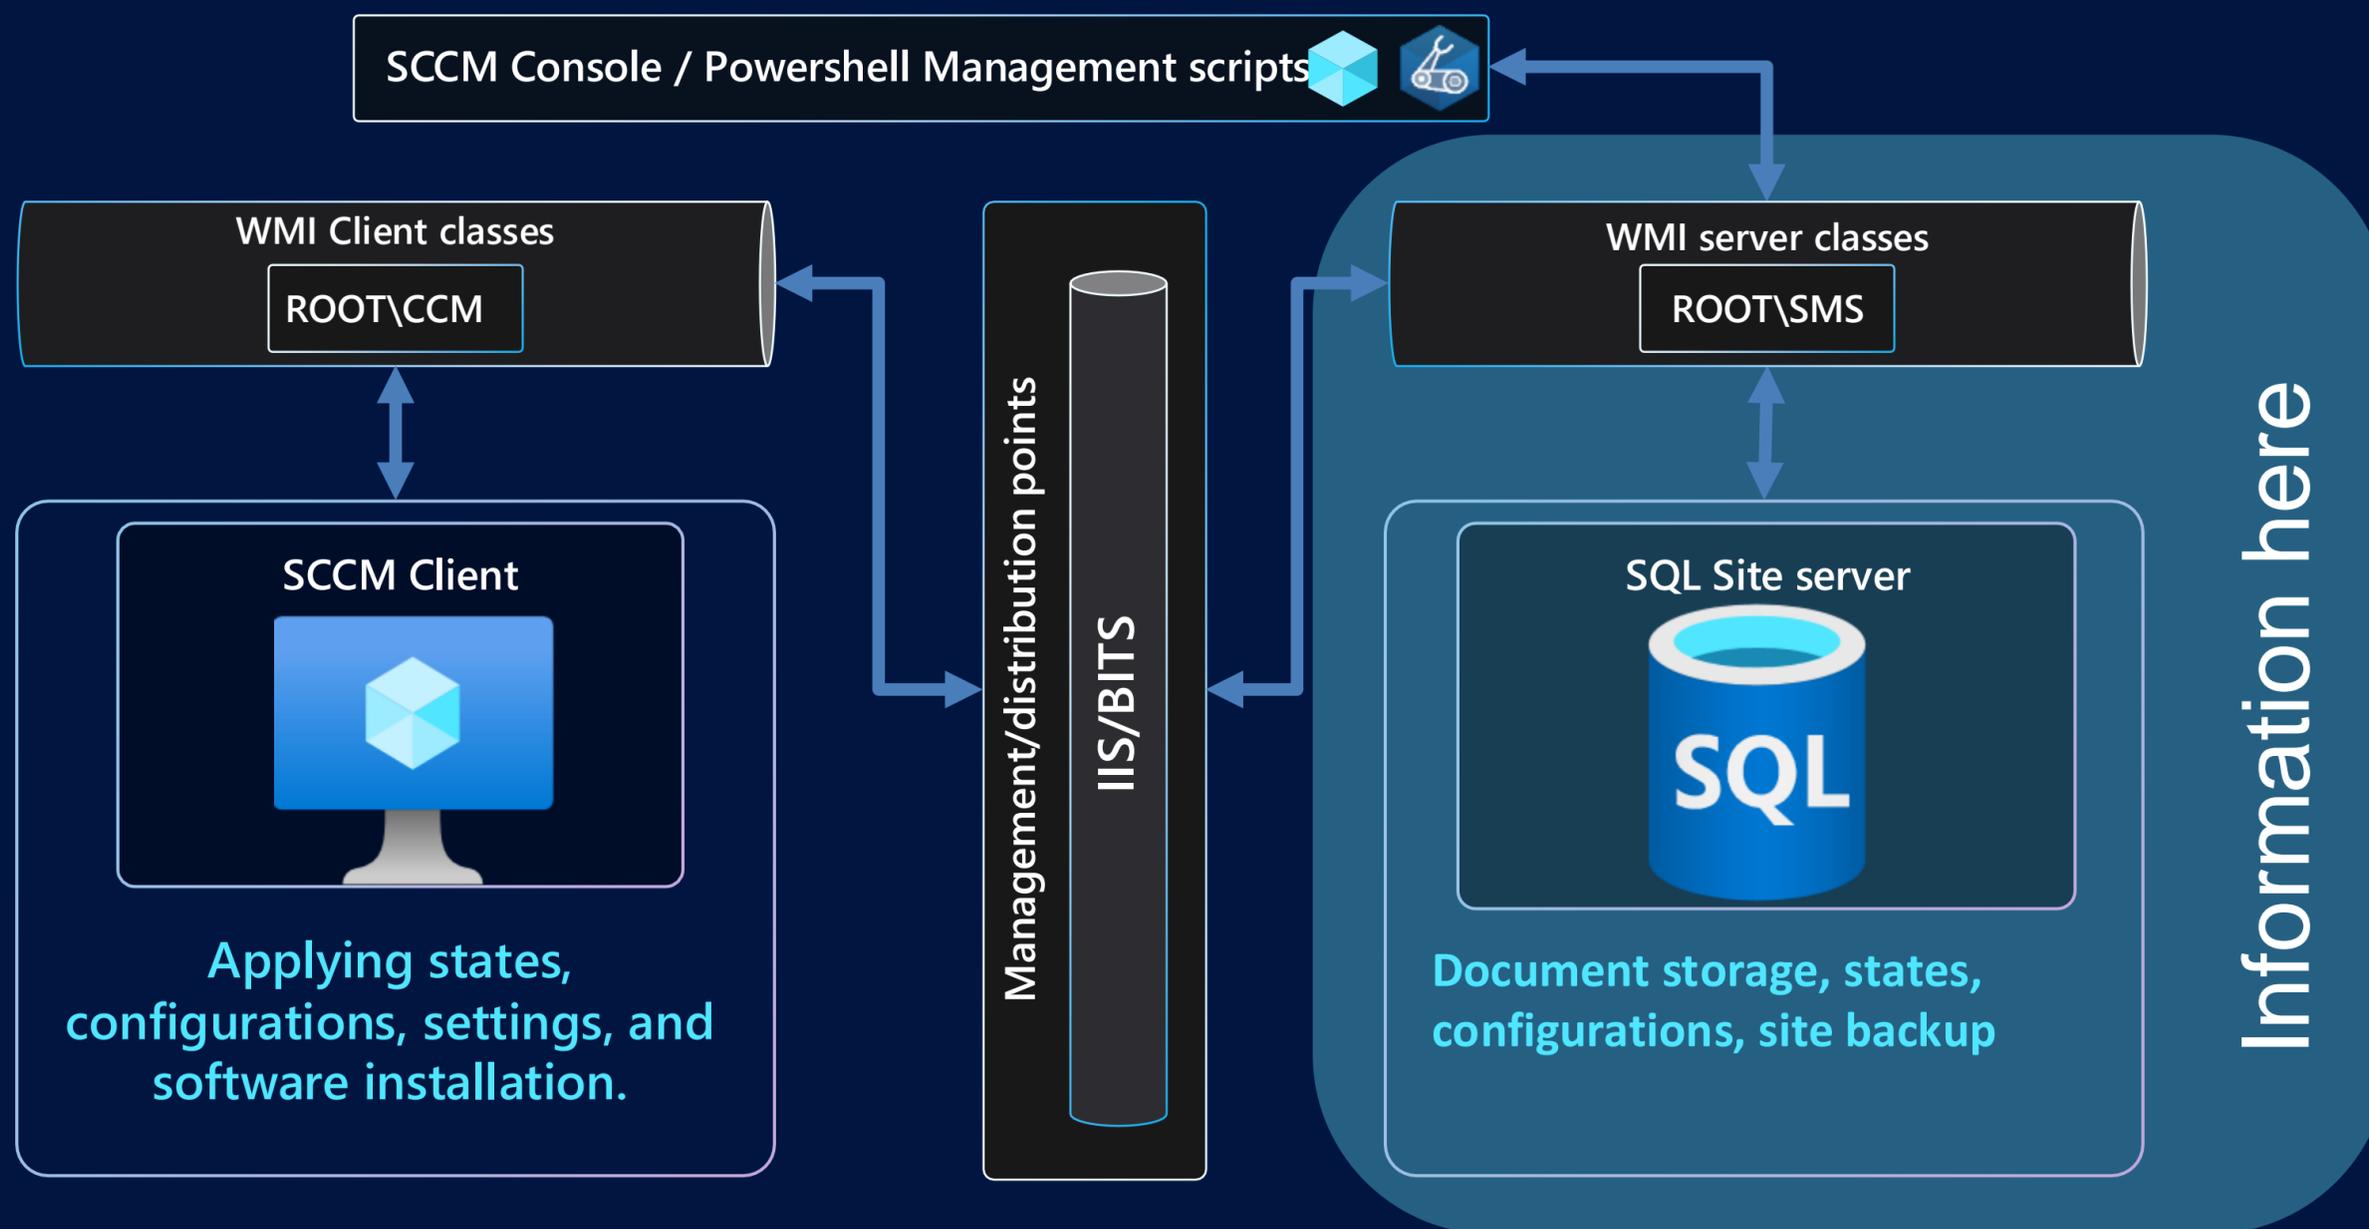

SCCM can do whatever you want  
That's why SCCM, like any complex system  
managing your infrastructure, should be  
consistently monitored.

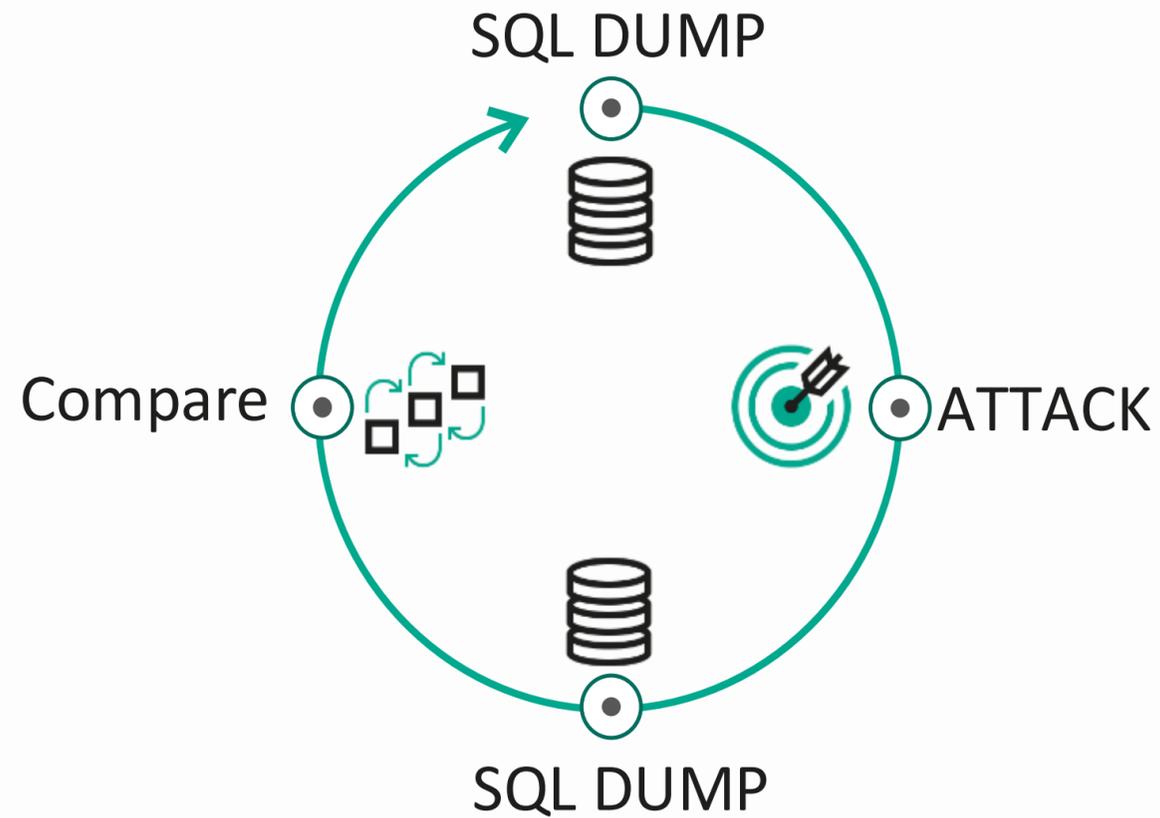

Due to SCCM's rich functionality that a dedicated «ATT&CK matrix» was created specifically for it.

<https://github.com/subat0mik/Misconfiguration-Manager>

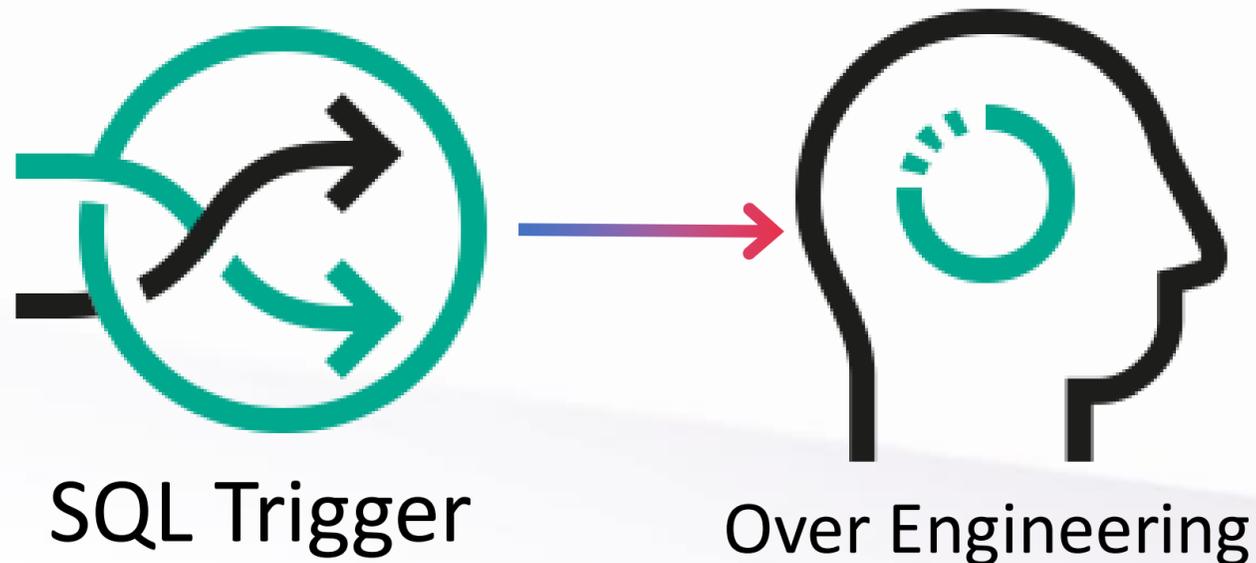

Initial Access	Execution	Persistence	Privilege Escalation	Defense Evasion	Credential Access	Discovery	Lateral Movement	Collection	Command and Control	Exfiltration
PXE Credentials	App Deployment	App Deployment	Relay to Site Server SMB	App Deployment	PXE Credentials	LDAP Enumeration	App Deployment	CMPivot		CMPivot
	Script Deployment	Script Deployment	Relay Client Push Installation	Script Deployment	Policy Request Credentials	SMB Enumeration	Script Deployment			
		ADCS Relay	Relay to DB MSSQL		DPAPI Credentials	HTTP Enumeration	Relay to Site Server SMB			
		LDAP Relay	Relay to DB SMB		Legacy Credentials	CMPivot	Relay Client Push Installation			
			Relay to ADCS				Relay to DB MSSQL			
			Relay to AdminService		Site Database Credentials		Relay to DB SMB			
			Relay CAS to Child				Relay CAS to Child			
			Relay to SMS Provider SMB				Relay to AdminService			
			Relay between HA				Relay to SMS Provider SMB			

This is a simplified architecture diagram of SCCM.

The obvious approach is to collect data from SQL, compare it, and look for suspicious changes. This is challenging because the SQL on the site server contains a **significant volume of information**, and the **relationships** between fields, tables, and views **are complex**. However, a **lot of forensic information** can be found in the document storage.

You can write an SQL trigger that will notify us of important changes in SCCM. However, this is **quite complex**: you need to understand the relationships between objects and views in the database. Nonetheless, you can leverage the **wealth of resources provided by the community**.

## SharpSCCM.exe exec -p "cmd /c ping.exe -t google.com" -n "All Systems"

When you create a Deployment Task that runs “ping Google.com” on each computer, the **malicious** command string appears in the site database only as an **embedded XML document** within a single column in the document storage.

Search: "ping.exe"

**Documents (4)** Field statistics

Document ID	Table Name	Document Type	Body
0	CI_DocumentStore		<AppMgmtDigest xmlns="http://schemas.microsoft.com/SystemCenterConf instance"><Application AuthoringScopeId="ScopeId_F25FB8B6-4C3E-4B5D a403e945b00c" Version="1"><DisplayInfo DefaultLanguage="en-US"><Inf 664e8</Title><Publisher /><Version /></Info></DisplayInfo><D B95FAEB6090A/DeploymentType_bce89e09-06f7-4788-a2cd-91feedf
	CI_DocumentStore		InstallCommandLine = "cmd /c ping.exe -t google.com" Execu RequiresUserInteraction = false; RequiresReboot = false; Us "BasedOnExitCode"; ExecuteTime = 0; MaxExecuteTime = 15; Ru
	CI_DocumentStore		(2010); HardRebootExitCode = (1641); SoftRebootExitCode

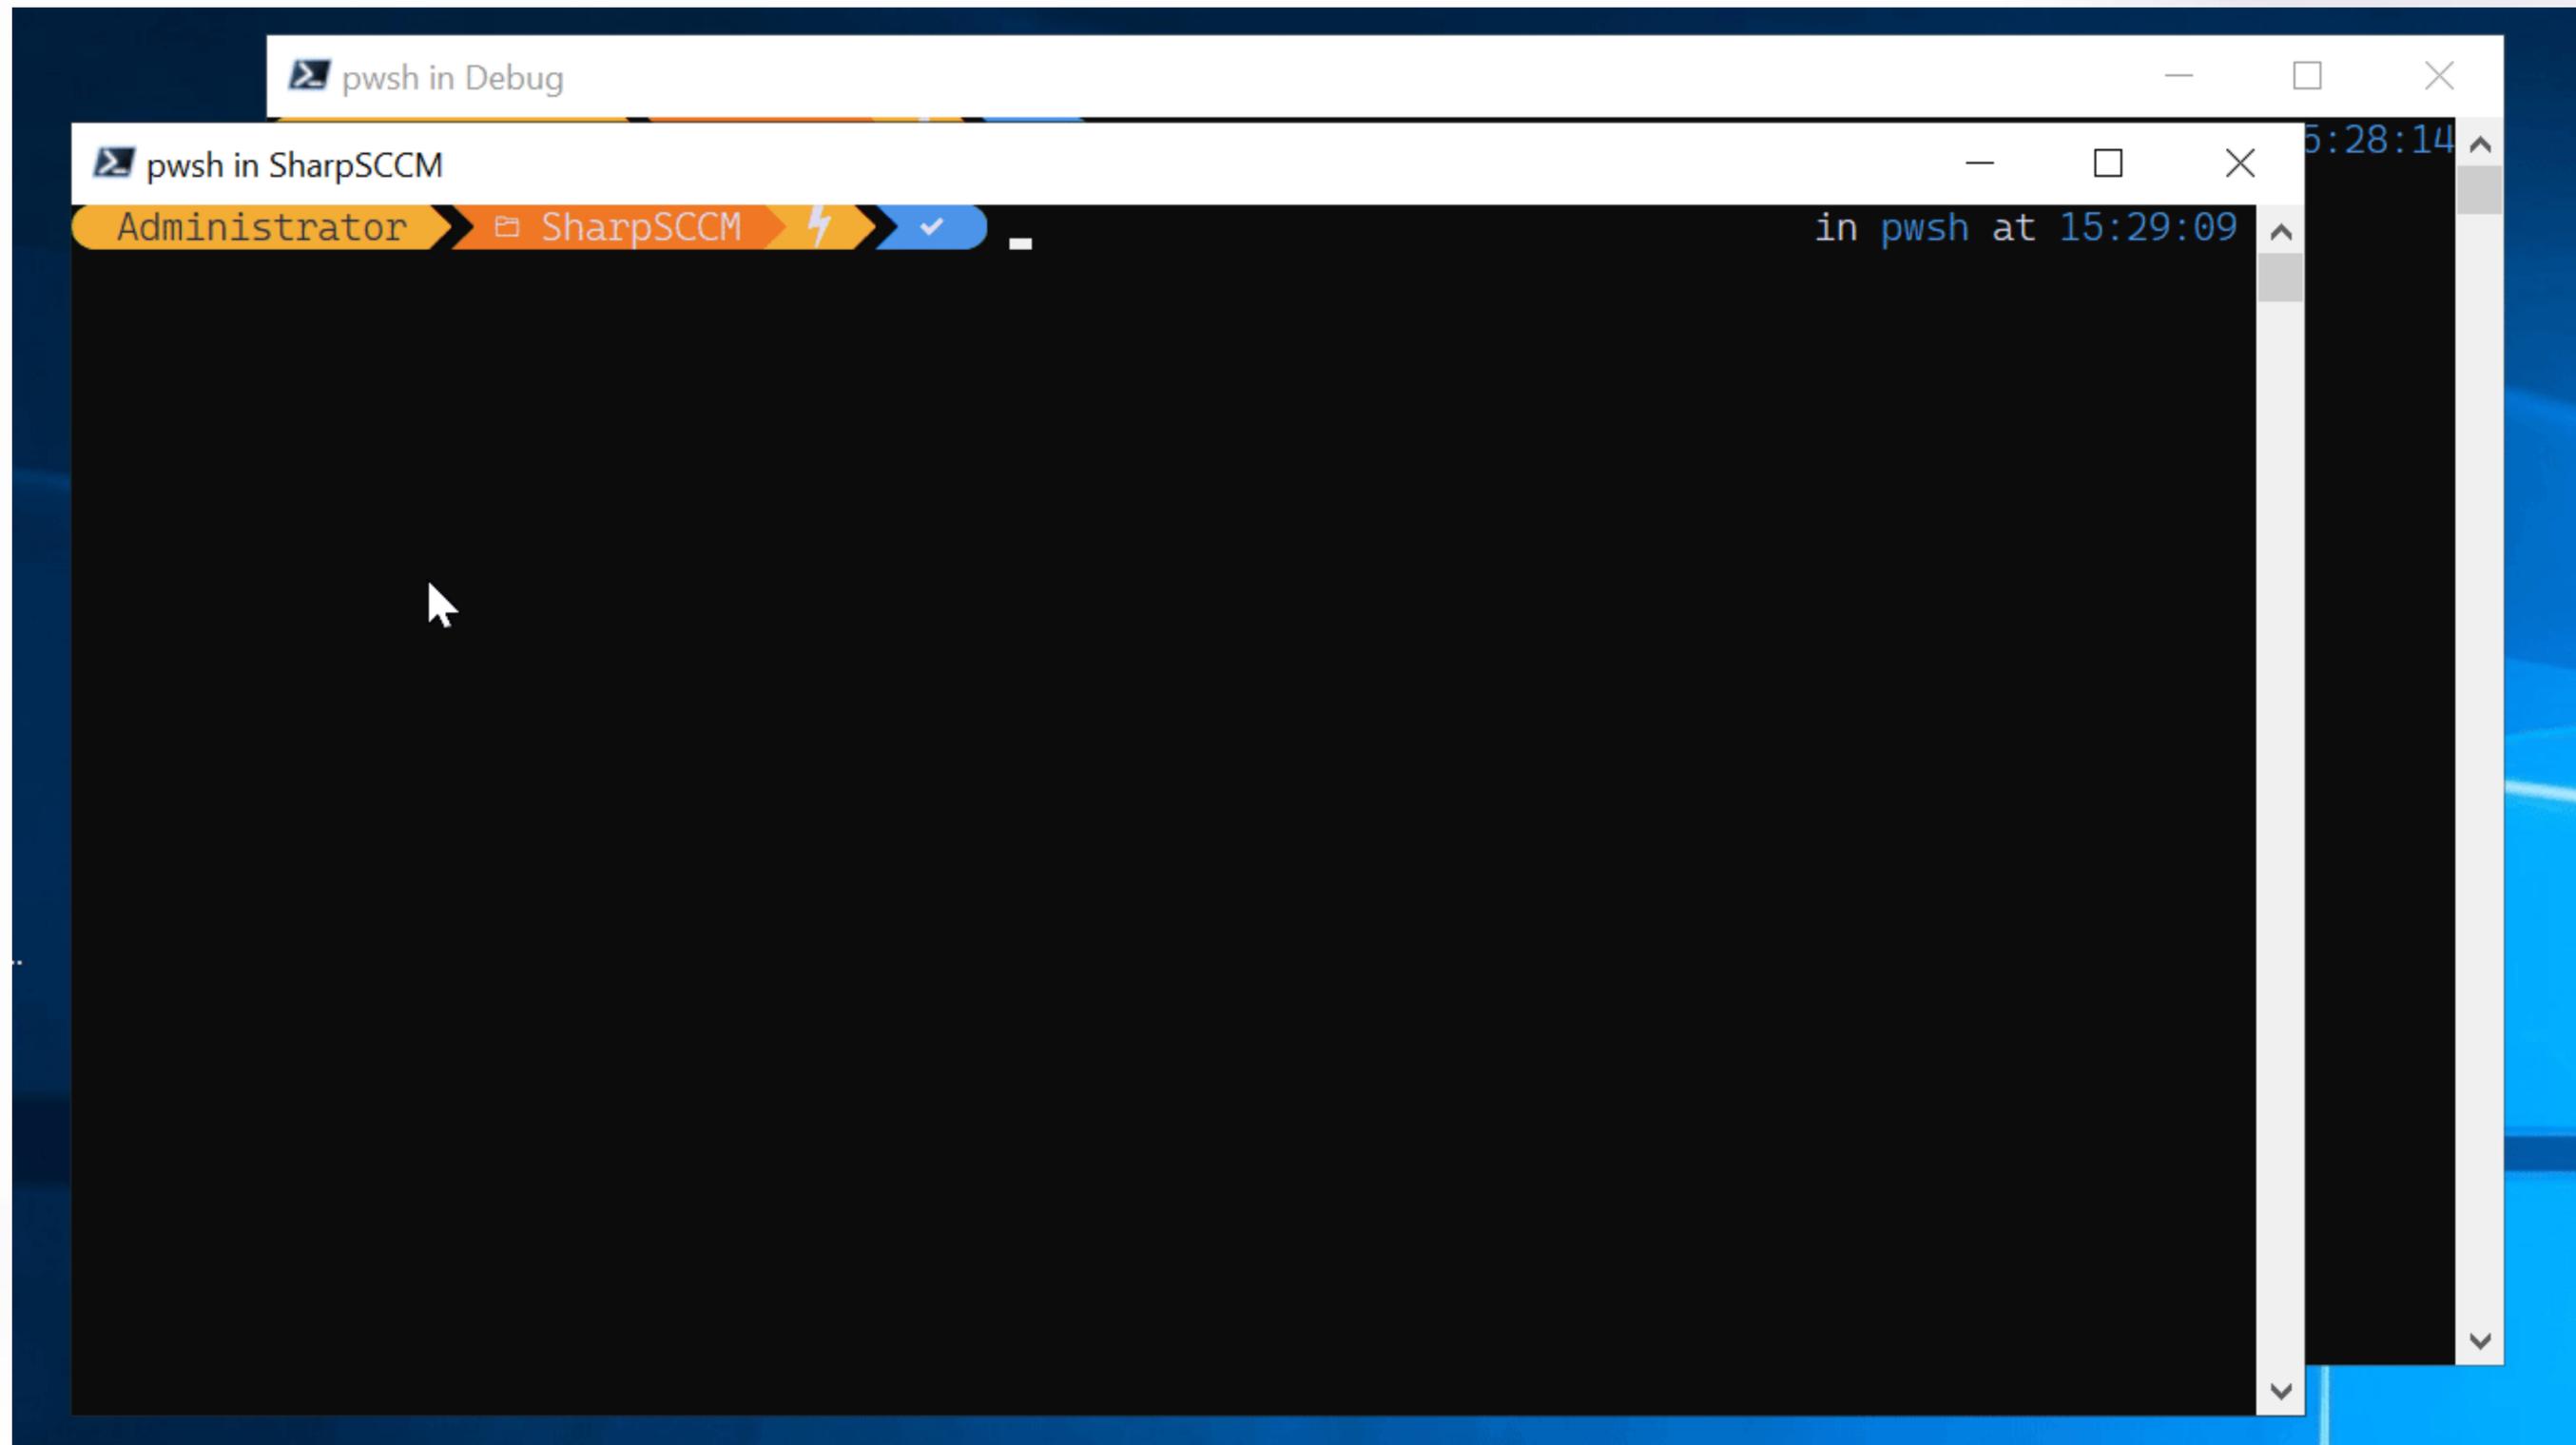

To monitor changes in SCCM, we will create WMI subscriptions that will notify us of any significant changes in SCCM. It is extremely configurable approach

EXEC-1 – Deployment was added

```
string [] classesToMonitor = {  
    "SMS_DeploymentInfo",  
    "SMS_CombinedDeviceResources",  
    "SMS_Admin",  
    "SMS_Scripts",  
    "SMS_SCI_Reserved"  
};
```

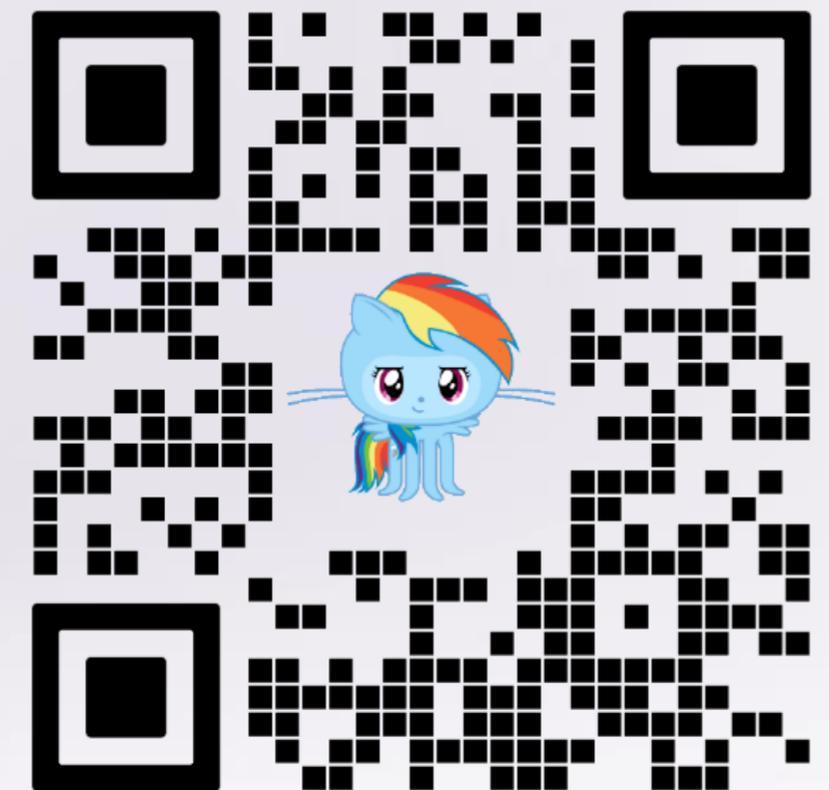

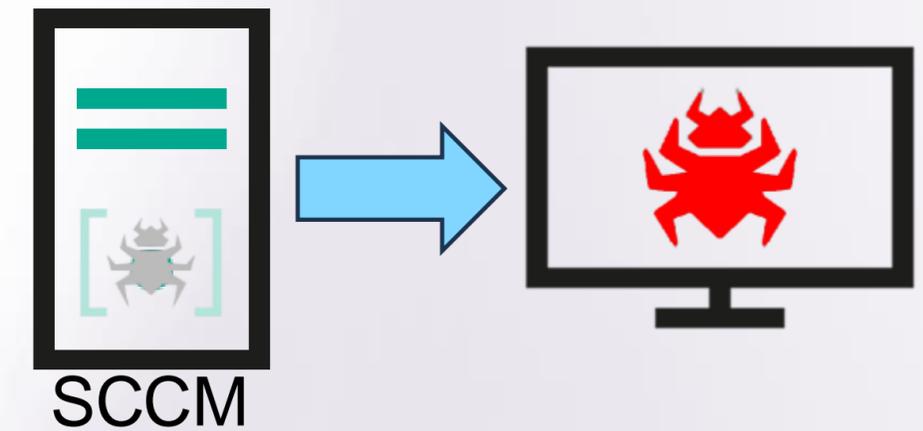

```
foreach (string className in classesToMonitor)  
{  
    WqlEventQuery query = new WqlEventQuery(  
        "__InstanceCreationEvent",  
        new TimeSpan(0, 0, 1),  
        $"TargetInstance ISA '{className}'");  
  
    ManagementEventWatcher _watcher;  
    _watcher = new ManagementEventWatcher(scope, query);  
    _watcher.EventArrived += new EventArrivedEventHandler(HandleEvent);  
    _watcher.Start();  
}
```

SCCM is a great example of how, in a distributed information system, a specific piece of software can be defined on **one** system yet executed on **another**.

This can be called the **distribution paradox**.

Only the SOC team can effectively correlate and monitor information within distributed systems.

Eventually, in the field of information security, you'll **face challenges that can't be handled by any automated systems** currently available in your infrastructure.

That's why it's essential to have monitoring centers and **Security Operations Centers (SOCs)** in place — they provide the expertise and oversight needed when automation alone isn't enough.

Security incident in the infrastructure of [REDACTED]

On *2024-06-13 03:58* (UTC) a suspicious software was found running on the host **ST** [REDACTED]

```
C:\Windows\System32\DiagSvcs\ApplicationDiagnosticsHub.exe  
MD5: 0x5F3BE4AEBAD49DE9256A0A5E95DB9822  
Original File name: cloudflared.exe
```

[Cloudflare Zero Trust Tunnel](#) is a service from [Cloudflare](#) that proxies traffic to your origin (e.g. a webserver or router), more information about its potential abuse and malicious usage is available in the following blog post:

- [CloudflareD AbuseD in the Wild](#)

This software was executed with following parameters:

It would be very **difficult** for an **automated tool to detect this**, because, depending on the context, **identical software with the same settings** could be used completely **legitimately**.

On the same day, several hours later, starting from 18:07:40 (UTC) an [UPX compressed RAR binary](#) was dropped into the host:

Path: C:\PerfLogs\Rar.exe

MD5: 0x7DA81965853F547858771FCCF78C3E02

Size: 125.50 KB (128512 B)

Curiously, the binary is the same one that was leaked from the [Shadowbrokers leak](#), available in the public domain.

Only an expert assessment by **an SOC specialist can clarify the importance** of a particular artifact. The SOC can **also** potentially **reduce** the perceived **significance** of certain artifacts.

High

Case #91 [REDACTED] - APT infiltration via dinotify.dll implant on three hosts

It is **just the title** of an incident case.

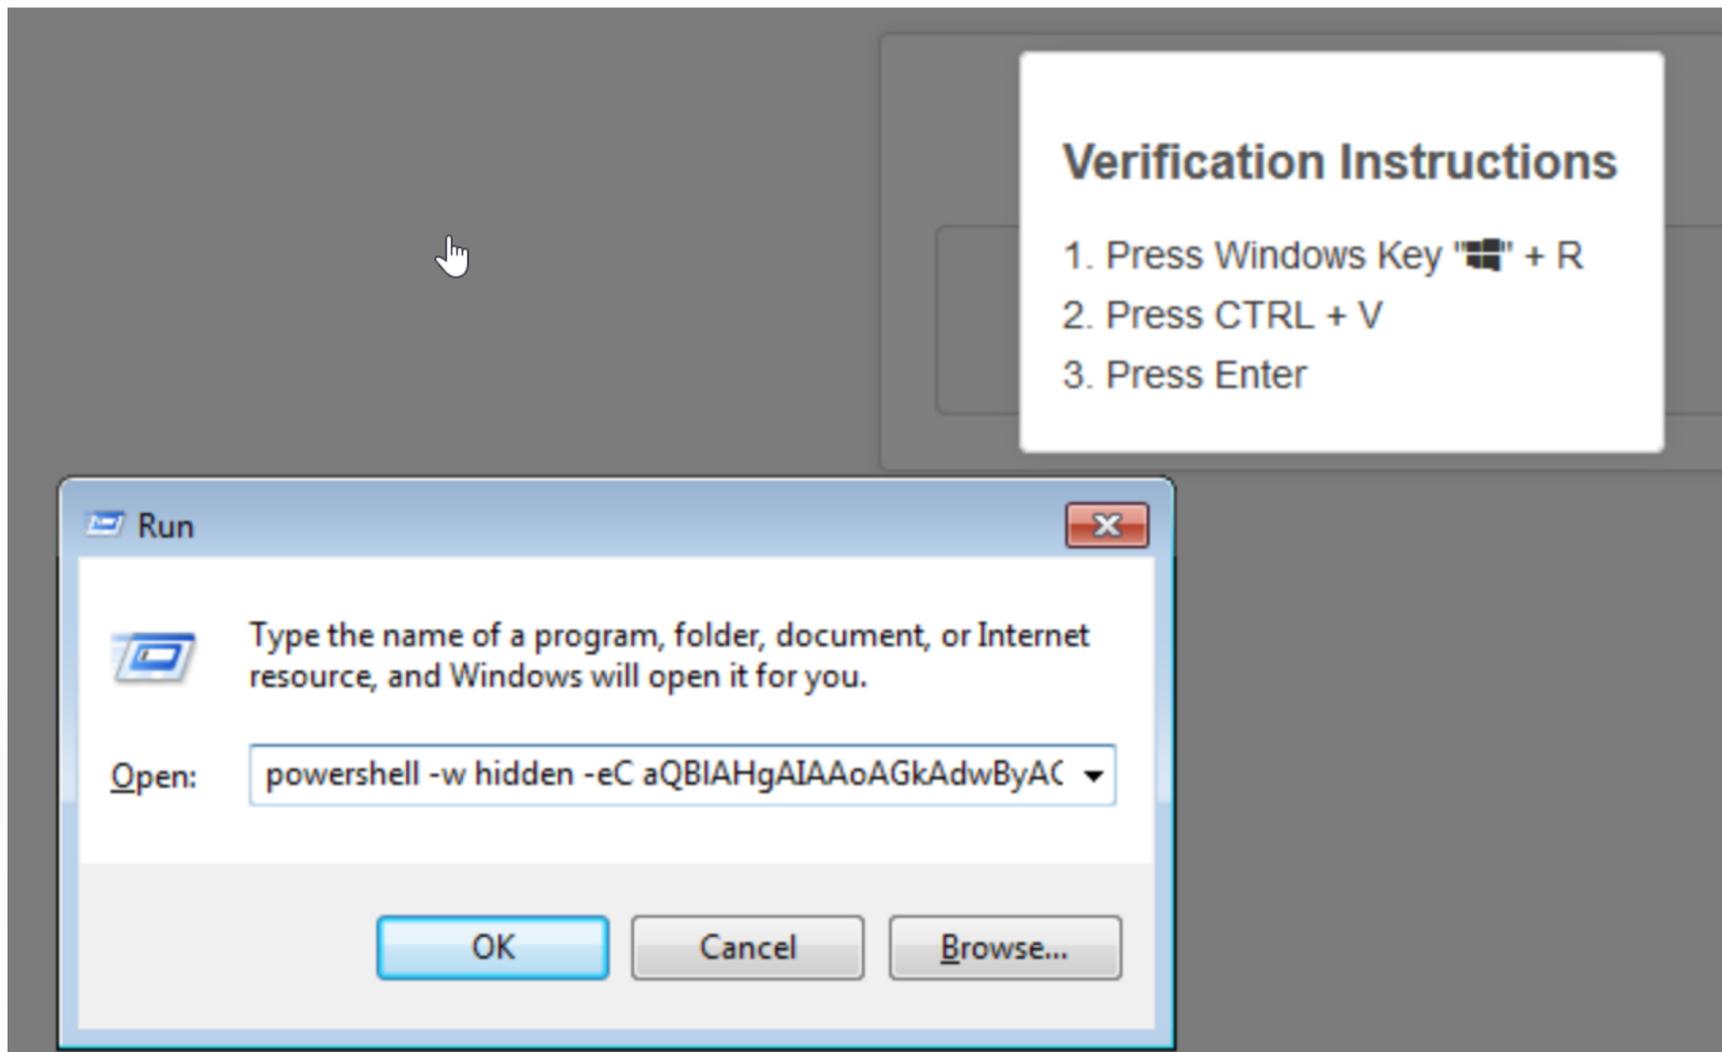

But we immediately see **importance** and **scale** of problem

Prioritization – great gift from SOC to your IT security

The activity originated from visiting `newvideozones[.]click/veri[.]html` which was accessed via browsing activity on `firefox.exe`.

The page is a fake CAPTCHA that is tricking the user into executing the command.

Below is a screenshot of the mentioned URL:

# Can explain things

# Conclusions

Just build\make\implement SOC

- It will bring new quality characteristics to your information security processes
- It will make your life easier (well, later, when everything settles down)
- It cool (the level of technology will increase)

Questions?

# Thank you!
